What is Heimlich Valve?

- **Heimlich valve** is a non-return valve that allows fluid and air to exit the thoracic cavity (on inspiration) and prevents fluid and air from re-entering (during expiration).
- **Heimlich valve** is used for patients who still need drainage of the thoracic cavity but no longer require hospitalization.
- **Heimlich valve** is a small tube with a non-return valve inside which is sterile and for single-use. Heimlich valve is connected to the catheter via the tapered connector.
- **Heimlich valve** is also available as a complete set with a pre-connected collection bag. The 2000 ml bag is equipped with tap to empty the liquid and an air vent valve to release air-leaks from patient.
